Diederich, P., A. M. Millanes, B. J. Coppins & M. Wedin, 2020. *Tremella imshaugiae* and *T. tubulosae* (Tremellomycetes, Basidiomycota), two new lichenicolous fungi on *Imshaugia aleurites* and *Hypogymnia tubulosa*. *Bulletin de la Société des naturalistes luxembourgeois* 122 : 239–246.

Published online 16 October 2020 (ISSN 2716-750X).

**Abstract.** The new *Tremella imshaugiae*, lichenicolous on *Imshaugia aleurites*, is described from Scotland and Maine (USA); it is characterized by small, 0.1–1 mm diam., amber coloured basidiomata not inducing gall-formation, 2–4-celled, mainly longitudinally septate basidia, 15.5–21.5 × 13–16.5 µm, and relatively large, subspherical basidiospores, 6.5–9 × 6.5–8.5 µm; it is sister to *T. diploschistina* in a phylogeny using ITS and nLSU markers. The new *Tremella tubulosae*, lichenicolous on *Hypogymnia tubulosa*, is described from Scotland and Spain; it is characterized by pale to dark brown or blackish basidiomatal galls, 0.2–1.8 mm diam., 2-celled, mainly longitudinally septate basidia, 10–17 × 8–11 µm, and medium-sized, subspherical to ellipsoid basidiospores, 6.5–8 × 5–6.5 µm; it is sister to *T. hypogymniae* in a phylogeny using ITS and nLSU markers.

## 1. Introduction

The genus *Tremella* Pers. includes over 200 mycoparasitic species, many being strictly host-specific. Diederich (1996) revised the lichenicolous taxa and accepted 46 species, amongst which six were left unnamed. More lichenicolous species have been described in subsequent papers, such as Diederich (2007) or Zamora et al. (2016), and a total number of 60 lichen-inhabiting species were accepted by Diederich et al. (2018). A first phylogenetic study of the lichenicolous species was presented by Millanes et al. (2011).

In this paper we will describe two new lichen-inhabiting species of *Tremella*, one

developing amber-coloured basidiomata on the thallus of *Imshaugia aleurites*, and the other inducing conspicuous galls on the thallus of *Hypogymnia tubulosa*. Both hosts are members of the Parmeliaceae.

## 2. Material and methods

### 2.1. Molecular studies

In addition to the specimens studied, 34 specimens representing 27 species in the Tremellales were included in the molecular study (Table 1). The sampling included (1) lichenicolous species growing on Parmeliaceae or closely related to the new species in preliminary phylogenetic analyses and

(2) a representation of the main filamentous and yeast families in the Tremellales, including the groups of lichenicolous *Tremella* species distinguished by Millanes et al. (2011). *Phaeotremella foliacea* was used as outgroup following Liu et al. (2016). *Phaeotremella* is the sister group to the rest of Tremellales, and our preliminary analyses showed that the new species were nested in *Tremella*, but not closely related to this genus. Species names, voucher information, and GenBank accession numbers are given in Table 1.

DNA extraction and PCR amplifications were achieved following protocols in Millanes et al. (2012).

Alignments and Bayesian analyses were conducted following Diederich et al. (2019). Likelihood models were selected for each of the four partitions with the corrected Akaike information criterion (AICc) as implemented in jModeltest (Posada 2008). A GTR+ $\Gamma$  model was selected for the ITS1, a K80+ $\Gamma$  for the 5.8S, a K80 + $\Gamma$  for the ITS2, and finally a GTR+ $\Gamma$  for the nLSU rDNA. Maximum likelihood analyses were achieved in IQ Tree v. 1.6.12 (Nguyen et al. 2015), using the same partitions and model selection than in the Bayesian analysis. We used edge-linked branch lengths between partitions but separate models between partitions (Chernomor et al. 2016). We assessed node support using standard non-parametric bootstrap with 1000 replicates. Significant support is considered as Bayesian posterior probability (BPP) values  $\geq 0.95$  in the Bayesian analysis, and bootstrap values  $\geq 75\%$  in the ML analysis.

## 2.2. Morphological examination

Dry herbarium specimens were examined and measured under a binocular microscope Leica MZ 7.5. Macroscopic photographs were done using a Canon 40D camera with a Canon MP-E 65 mm lens or a Nikon BD Plan 10 $\times$  microscope objective, StackShot (Cognisys) and Helicon Focus (HeliconSoft) for increasing the depth of field. Hand-made sections of basidiomata

were studied in a mixture of Phloxine B and 5% KOH. Microscopic photographs were prepared using a Leica DMLB microscope with DIC optics and a Leica EC3 camera. Measurements of basidia and basidiospores are indicated as (min.) $\bar{X}$ - $\sigma_x$ - $\bar{X}$ + $\sigma_x$  (-max.), followed by the number of measurements (n); the ratio length/width of basidia and basidiospores is indicated as l/w and given in the same way; basidial length designates the distance from the basidial base to the top, but excluding the epibasidia; basidiospores width is measured without the apiculus; in both cases, the 'length' may be shorter than the 'width'; in the diagnoses, measurements are rounded to the nearest 0.5  $\mu$ m.

## 3. Results

### 3.1. Phylogenetic results

We generated 12 new sequences that were aligned together with sequences already available in GenBank (Table 1). The combined matrix contained 1269 characters (ITS1: 1–81; 5.8S: 82–234; ITS2: 235–362; nLSU: 363–1269). BI was halted after 2 300 000 generations, at which time the average standard deviation of split frequencies across runs was below 0.01, which indicates that the three runs had converged. Moreover, the potential scale reduction factor (PSRF) for all models and parameters was below 1.002. A majority rule consensus tree was constructed from the 11500 trees of the stationary tree sample from the Bayesian analysis. The best tree obtained from the ML analyses had a log-likelihood value of -7591.9780. No incongruence was found between the Bayesian and ML trees. Therefore only the Bayesian tree is shown in Fig. 1.

The new species *Tremella tubulosae* is the sister taxon to *T. hypogymniae* Diederich & M. S. Christ. and forms a clade together with other lichenicolous taxa growing on Parmeliaceae, called "Clade III" in Millanes et al. (2011) (Fig. 1). The new species *Tremella imshaugiae* is the sister taxon to *Tremella diploschistina* Millanes, M. Westb., Wedin & Diederich.

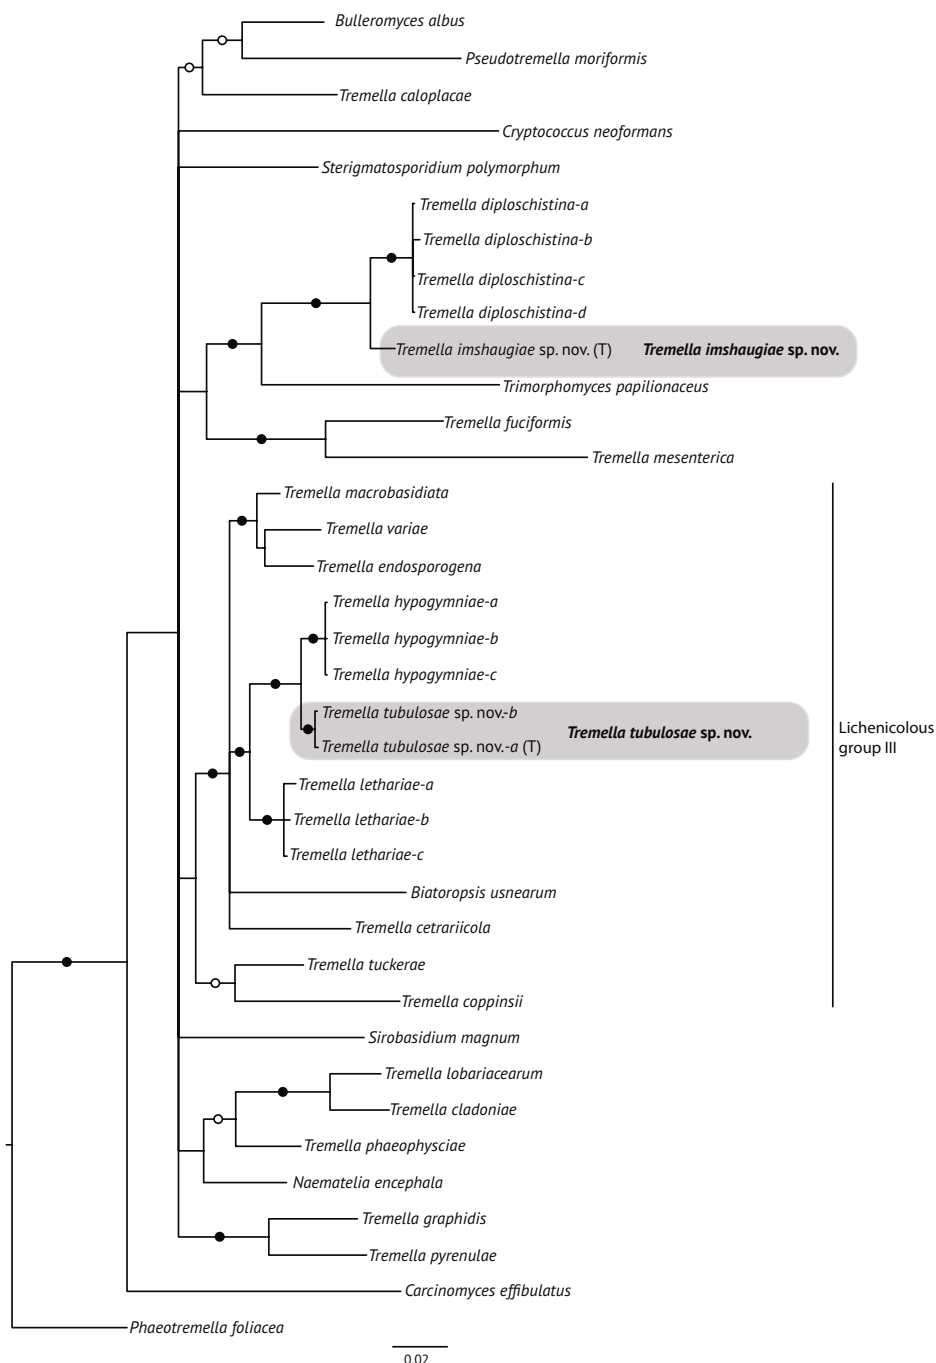

Fig. 1. Fifty per cent majority rule Bayesian consensus tree with average branch lengths from the combined analyses of ITS and nLSU datasets. White dots indicate PP values  $\geq 0.95$ , obtained in the Bayesian analysis. Black dots indicate PP values  $\geq 0.95$ , and bootstrap values  $\geq 75\%$ . Branch lengths are scaled to the expected number of nucleotide substitutions per site. The new species *Tremella tubulosae* and *T. imshaugiae* are enclosed in grey boxes. Type specimens of the new species are indicated with (T). The clade corresponding to “Clade III” in Millanes et al. (2011) is indicated to the right.

Table 1. Sequences newly produced (bold), and sequences downloaded from GenBank, with specimen data or culture references given. Type specimens or strains are indicated with (T).

3.2. Taxonomy

***Tremella imshaugiae* Diederich, Coppins, R. C. Harris, Millanes & Wedin, sp. nov. (Fig. 2)**

Mycobank MB837687

Lichenicolous on the thallus of *Imshaugia aleurites*; characterized by small, 0.1–1 mm diam., amber coloured basidiomata not inducing gall-formation, 2–4-celled, mainly longitudinally septate basidia, 15.5–21.5 × 13–16.5 µm, and relatively large, subspherical basidiospores, 6.5–9 × 6.5–8.5 µm.

Type: UK, Scotland, VC 96, Easternness, Glen Feshie, Allt Fhearnagan, 27(NN)/858 971, 410 m, on *Pinus* twig, on *Imshaugia aleurites*, 3 xi 2013, H. Paul (E 00722344 – holotype).

**Basidiomata** not gall-inducing, amber coloured, convex, gelatinous, often fusing, 0.1–1 mm diam. **Context hyphae** thin-walled, often with clamp connections, 2–3  $\mu$ m diam.; haustorial branches present, mother cells subspherical, 2.5–4.5  $\times$  2.5–4  $\mu$ m, haustorial filament 1–1.5  $\mu$ m diam. **Hymenium** hyaline, containing numerous probasidia; hyphidia not observed; probasidial initials clavate, proliferations occurring through the basal clamp; fertile hyphae 2.5–5  $\mu$ m thick. **Basidia**, when mature, 2–4-celled, with longitudinal, rarely oblique septa, slightly constricted at the septa, not stalked, (13.5–)15.7–21.3(–28.0)  $\times$  (11.3–)12.9–16.5(–20.3)  $\mu$ m, ratio l/w (0.9–)1.0–1.5 (–2.0) (n=45); epibasidia subcylindrical, up to at least 32  $\mu$ m long, 4–7  $\mu$ m diam. **Basidiospores** subspherical, with a distinct apiculus, (5.7–)6.6–9.0(–10.0)  $\times$  (5.8–)6.4–8.6(–9.5)  $\mu$ m, ratio l/w (0.9–)0.9–1.1(–1.2) (n=33). **Anamorph** not observed.

**Distribution and host.** Known from two Scottish localities and from Maine, USA, always on the visibly undamaged thallus of *Imshaugia aleurites*.

**Discussion.** *Tremella diploschistina*, the sister species in our phylogeny (Table 1), differs by 2-celled basidia and a hymenium containing numerous thick-walled hyphidia (Millanes et al. 2012). Amongst the known lichenicolous *Tremella* species with 2–4-celled, non-stalked basidia with distinct, not gall-inducing, amber coloured basidiomata developing over the host thallus, *T. graphidastrae* Diederich is distinguished by much smaller basidiospores, 5.5–7  $\times$  3.5–5  $\mu$ m, and smaller basidia, 14.5–17  $\times$  11–12.5  $\mu$ m; *T. wirthii* Diederich is distinguished by pale to dark greyish brown basidiomata; *T. haematommatis* Diederich has much larger basidia, 15–36  $\times$  11–20  $\mu$ m; *T. coppinsii* Diederich & Marson is distinguished by reddish ascomata, much smaller basidia, 8–13  $\times$  5–12  $\mu$ m, and ellipsoid basidiospores, 6–10  $\times$  4–6.5  $\mu$ m (Diederich 1996). *Tremella nashii* Diederich has pale to dark brown

basidiomata and smaller basidiospores, 5–8  $\times$  4–6  $\mu$ m (Diederich 2007).

**Additional specimens examined** (all on *Imshaugia aleurites*): **UK:** Scotland, VC 92, South Aberdeen, E of Braemar, Creag Clunie & Lion's Face SSSI, E side of Creag Clunie, valley of Allt na Claise Moire, 37/18.90, 350 m, 9 iv 1999, Coppins 18234 (E 00722368). – **USA:** Maine, Washington Co., Town of Beals, Great Wass Island, Great Wass Island Preserve, 44°28'51" N, 67°35'41" W, coastal conifer forest, 29 vi 2012, Harris 57529 (NY 1595942).

***Tremella tubulosae* Diederich, Coppins, J. C. Zamora, Millanes & Wedin, sp. nov. (Fig. 3)**

Mycobank MB837688

Lichenicolous on the thallus of *Hypogymnia tubulosa*, gall-inducing; characterized by pale to dark brown or blackish basidiomatal galls, 0.2–1.8 mm diam., 2-celled, mainly longitudinally septate basidia, 10–17  $\times$  8–11  $\mu$ m, and medium-sized, subspherical to ellipsoid basidiospores, 6.5–8  $\times$  5–6.5  $\mu$ m.

Type: UK, Scotland, VC 92, South Aberdeen, Glen Fenzie, 38(NJ) 318 030, on *Juniperus*, on *Hypogymnia tubulosa*, 1 iv 2008, B. J. Coppins 22916 & C. J. Ellis (E 00722365 – holotype).

**Basidiomata** inducing the formation of distinct, convex galls on the host thallus, base not constricted, pale to dark brown or blackish, matt, 0.2–1.8 mm diam. **Context hyphae** thin-walled, 2–3  $\mu$ m diam., clamp connections not observed; haustorial branches present, mother cells subspherical, c. 5  $\times$  4.5  $\mu$ m, haustorial filament 1–1.5  $\mu$ m diam. **Hymenium** hyaline, containing numerous probasidia; hyphidia not observed; probasidial initials clavate, proliferations occurring through the basal clamp; fertile hyphae 2–5  $\mu$ m thick. **Basidia**, when mature, 2-celled, with one longitudinal, rarely oblique or transverse septum, slightly constricted at the septum, not or slightly stalked, (6.9–)10.0–16.9(–23.0)  $\times$  (7.0–)7.8–10.8(–14.7)  $\mu$ m, ratio l/w (0.8–)1.0–1.9(–2.6) (n=28), rarely with an attenuated stalk-like base; epibasidia subcylindrical, up to at least 40  $\mu$ m long, 2.5–4.5  $\mu$ m diam. **Basidiospores** subspherical to ellipsoid, with a distinct apiculus, (5.8–)6.6–7.8(–8.3)  $\times$  (4.9–)5.2–6.6(–7.9)  $\mu$ m, ratio l/w (0.9–)1.1–1.4(–1.6) (n=35). **Anamorph** not observed.

*Distribution and host.* Known from three localities in Scotland and one in Spain,

always on the thallus of *Hypogymnia tubulosa*, gall-inducing.

Fig. 2. *Tremella imshaugiae* (A–B, Coppins 18234; C, E–H, holotypus; D, Harris 57529; E–H in a mixture of Phloxine B and 5% KOH). A, Thallus of *Imshaugia aleurites*, with numerous small, amber coloured basidiomata in the upper right part. B–D, Basidiomata at a higher magnification. E–F, Hymenium with basidia. G, Haustorial branches. H, Basidiospores, the two lower ones germinating. Scale bars: A = 1 mm, B–D = 200 µm, E–F = 10 µm, G–H = 5 µm.

*Discussion.* The new species is phylogenetically distinct and sister to *Tremella hypogymniae*, known from *Hypogymnia physodes* (thallus); that species is distinguished by pale brown or orange to pinkish basidiomatal

galls, becoming blackish only in the presence of other lichenicolous fungi, and by slightly larger basidiospores,  $7\text{--}10 \times 5.5\text{--}7\ \mu\text{m}$  (Diederich 1996). *Tremella papuana* Diederich, described from *Hypogymnia pseudobitteri-*

Fig. 3. *Tremella tubulosae* (A–D, G–J, holotypus; E, Coppins 18843; F, Coppins 18906; G–J in a mixture of Phloxine B and 5% KOH). A–C, Development of basidiomatal galls on the thallus of *Hypogymnia tubulosa*. D–F, Mature basidiomata. G, Hymenium with basidia. H, Basidia. I, Basidiospores. J, Haustorial branch. Scale bars: A–C = 200  $\mu\text{m}$ , D–F = 1 mm, G = 10  $\mu\text{m}$ , H–J = 5  $\mu\text{m}$ .

*ana*, has basidiomata constantly darker in the centre, usually smaller, 0.2–0.5 mm diam., and frequently narrower basidiospores, 3.5–6 µm wide (Diederich 1996).

Amongst the known lichenicolous *Tremella* species with rarely stalked, 2-celled, mainly longitudinally septate basidia, with cells not becoming elongate at maturity, without conspicuous hymenial hyphidia, inducing gall formation on the host thallus, with galls basally not constricted, pale brown when young and dark brown to blackish when old, *Tremella nephromatis* Diederich has distinctly larger, dark reddish brown basidiomata, up to 4 mm diam.; *T. coccocarpiæ* Diederich and *T. microcarpa* Diederich have very small basidiomata, < 0.2 mm diam.; *T. macroceratis* Diederich & Hafellner has narrower basidiospores, 4–5.5 µm wide and shiny basidiomata; and *T. montis-wilhelmii* Diederich and *T. normandinae* Diederich have pale to pinkish or reddish brown basidiomatal galls never turning dark brown or black (Diederich 1996).

*Additional specimens examined* (all on *Hypogymnia tubulosa*): **Spain**: Castilla y León, Segovia, San Ildefonso, next to road CL-601 at Las Siete Revueltas, entrance to Ramal de Vaquerizas, following Venerillo stream, 40°49' N, 4°0' W, on *Pinus sylvestris*, 18 ii 2012, Zamora, Pérez-Ortega & Millanes s.n. (S). – **UK**: Scotland, VC 95, Moray, Culbin Forest, 28/995.630, < 10 m, on pine twigs, 6 v 1999, Coppins 18843 (E 00722360); VC 107, East Sutherland, Loch Fleet NNR, Ferry Links, 28/80.95, < 10 m, on *Calluna*, 10 viii 1999, Coppins 18906 (E 00722345).

## Acknowledgments

We thank the curators of E and NY for the loan of specimens, Heather Paul for successfully fulfilling a request to find fresh material of *T. imshaugii*, and Damien Ertz for critically reading the manuscript. This paper was financially supported by the Swedish Taxonomy Initiative (Svenska Artprojektet, administered by the Swedish Species Information Centre/ArtDatabanken, STI dha 2016-27 4.3) and the Swedish Research Council (VR 2016-03589) through grants to M. Wedin, and by the Spanish Ministry of Economy and Competitiveness (CGL2016-80371-P) through a grant to A. Millanes. The Laboratory of Molecular Systematics (MSL) at the Swedish Museum of

Natural History, in particular Bodil Cronholm, is warmly thanked for excellent technical support.
